### ABSTRACT

Biological synthesis of nanoparticles is a promising approach that is comparatively inexpensive and eco-friendly. Among various microorganisms, actinobacteria have been found to be efficient in the synthesis of nanomaterials. In this study, extracellular biosynthesis of silver nanoparticles (Ag-NPs) was investigated by mixing silver nitrate with culture filtrate of *Streptomyces rochei* strain MFA-37. The biosynthesized Ag-NPs were characterized by UV–Vis spectrophotometric analysis, and showed a peak of absorbance at 440 nm. Fourier transform infrared (FTIR) analysis showed amines and amides that are responsible for the stabilization of Ag-NPs. The morphology and size of nanoparticles were determined using high-resolution transmission electron microscopy, XRD and DLS techniques which indicated well dispersed, spherical Ag-NPs sized 2–20 nm, and the zeta potential of AgNPs reached -20.5 mV. Enhancement of antibacterial activity of fourteen antibiotics was conducted by combining antibiotics with synthesized AgNPs. The synergistic activities of AgNPs combination with antibiotics were determined using disc diffusion against two multi-drug resistant *Staphylococcus aureus* SA-185 and SA-325 recovered from Libya. The highest synergistic effects were 6.11 and 6.37 folds for Penicillin followed by 6.11 and 4.44 folds for Ciprofloxacin and 6.11 and 3.69 folds for Erythromycin for MRSA-185 and MRSA-325, respectively. This activity of AgNPs and antibiotics could be valuable for the manufacture of hybrid drugs to kill or inhibit the MRSA infection especially in case of superficial injuries.

**Key words:** MRSA, Ag-NPs, Antibiotics, synergistic effects.

### INTRODUCTION

The widespread use of antibiotics to treat bacterial infections has resulted in the emergence of resistant forms of these organisms. Particularly, methicillin-resistant *S. aureus* (MRSA) which is a major concern, as it reduces the antibiotic treatment options for both prevention and cure and ultimately lead to prolonged patient hospitalization, increased mortality and treatment costs (Iram *et al.*, 2015). Its remarkable ability to acquire antibiotic resistance has contributed to its emergence as an important pathogen in a variety of

settings (Daini & Akano, 2009). So, studies are greatly required in finding out new antimicrobial agents against methicillin resistant *Staphylococcus aureus* (MRSA). One of the promising methods for overcoming bacterial resistance is the use of metallic nanoparticles (Allahverdiyev *et al.*, 2011). Ag-NPs are well known for their striking antimicrobial activity, and most of the synthesized Ag-NPs exhibit their major application as an anticancer, antioxidant and antimicrobial agents (Składanowski *et al.*, 2017). Unfortunately, convenient chemical and physical techniques have several

disadvantages, such as the use of toxic chemicals, high energy requirements, and difficult purification steps (Begum *et al.*, 2009). Biological synthesis of metal nanoparticles has been well achieved by various microorganisms (Golinska *et al.*, 2014; Zarina & Nanda, 2014). Actinobacteria are considered as an important resource for new products of medical and industrial interest such as antimicrobial agents (Bhosale *et al.*, 2015; Mohamedin *et al.*, 2015). *Streptomyces sp* is one of the genera of Actinobacteria, an efficient producer of bioactive compounds like antibiotics and nanoparticles which can be formed extracellularly and intracellularly, with a wide range of activities (Karthik *et al.*, 2014; Lakshmi *et al.*, 2015). The growing resistance of pathogenic bacterial strains to traditional antibacterial treatments has encouraged alternate strategies to control infections. One of these alternative strategies is combinatorial therapy, the combination of antibiotics and metal nanoparticles has numerous benefits that include increase the antibiotics' efficacy against resistant pathogens (Li *et al.*, 2005; Fayaz *et al.*, 2010). Moreover, nanoparticle-antibiotic combination lowers the amount of both agents in the dosage, which reduces toxicity and increases antimicrobial properties. Additionally, due to this combination, the concentrations of antibiotics were increased at the place of antibiotic-microbe contact and thus accelerated the binding between microbes and antibiotics preventing need for long term antibiotic use, prevent emergence of multidrug resistant bacteria (Allahverdiyev *et al.*, 2011). Up till now few reports are available on synergistic bactericidal activity of inorganic nanomaterials in combination with beta lactam antibiotics as penicillin and to the best of our knowledge synergistic activity of AgNPs nanoparticles with penicillin have not yet been thoroughly

investigated. In this article, we attempted to synthesize, characterize, and evaluate antimicrobial activity of Ag-NPs synthesis using *Streptomyces rochei* strain MFA-37 isolated from Egypt, moreover study synergistic effect of Ag-NPs combined with antibiotics against multidrug-resistant *Staphylococcus aureus* recovered from Libya.

## MATERIALS AND METHODS

### Soil sample collection and isolation of actinobacteria

Soil samples were collected from cultivated soil in Dakahleya, Egypt during April 2017. 20 g of the soil was air-dried for 3 days at room temperature. Isolation and purification of Actinobacteria isolates were performed according to Tsao *et al.* (1960).

### Screening of Ag-NP synthesizing actinobacteria

The preparation of cell-free supernatant and the biosynthesis of Ag-NPs were performed according to El-Naggar *et al.* (2016). The biosynthesis of AgNPs can be inferred by a color change from pale yellow into brown color and confirmed with UV-visible absorbance of the reaction mixture in the 300–600nm range (El-Naggar *et al.*, 2016). The potent isolate selected for further characterization.

### Characterization of the selected actinobacterial isolate

The selected isolate MFA-37 was characterized by light microscope (Optika, Italy) using slide culture technique and transmission electron microscopy (JEOL Technics Ltd, Japan) at the Regional Center for Mycology and Biotechnology, Al-Azhar University, Cairo. It was also characterized physiologically and biochemically according to (Holt *et al.*, 1994). Molecular identification was done using 16S rDNA analysis according to Atta *et al.* (2011).

### Biosynthesis and purification of silver nanoparticle

Ag-NPs was prepared as mentioned above using the supernatant of the selected strain MFA-37. The silver ions reduction was indicated via visual observation of color and by monitoring the UV-Vis spectra (Abd-Elnaby *et al.*, 2016). The obtained Ag-NPs was purified by centrifuged and washed with deionized water, the Ag-NPs were dried using a hot air oven at 60°C until a constant weight was obtained (Singh *et al.*, 2013).

### Characterization of Ag-NPs

The opto-electronic properties of the biosynthesized Ag-NPs were measured by ultraviolet-visible absorption spectra (UV-vis, Hitachi U-2800) in the range of 200–800 nm. The Fourier transform infrared spectroscopy (FTIR) spectrum of the sample was recorded on a Agilent system Cary 630 FTIR model –Chemistry Department, Faculty of Science, Al-Azhar University, Cairo, Egypt, in the range 400–4,000 cm<sup>-1</sup> in FT-IR spectroscopy at a resolution of 1 cm<sup>-1</sup>. The spectral data obtained were compared with the reference chart to identify the functional groups present in the sample. The size and shape of the products were observed by High-resolution transmission electron microscopic (HR-TEM) (JEOL 2100 Japan, at National Research Center (NRC), Giza, Egypt). The crystalline structure of the biosynthesized AgNPs was characterized by X-Ray diffraction that was carried out using the Shimadzu apparatus with nickel-filter and Cu-Ka target, Shimadzu Scientific Instruments (SSI), Kyoto, Japan. The particle size distribution of AgNPs was evaluated using Dynamic Light Scattering (DLS) measurement conducted with a Malvern Zetasizer Instrument. Measurements were taken in the range

between 0.1 and 1000 µm. Data obtained were analyzed using Zetasizer software. The XRD and DLS were measured at the National Center for Radiation Research and Technology (NCRRT), Cairo, Egypt. Zetasizer Nano ZS, Malvern, UK was used to characterize the zeta potential of the nanoparticles in the solution. Data were obtained and analyzed using Zetasizer software, samples were examined at Nawah-Scientific center, Almokattam, Cairo, Egypt. Generally, Characterization of AgNPs were carried out according to (Anandalakshmi *et al.*, 2016).

### Antibacterial activity of AgNPs

Multidrug resistant *Staphylococcus aureus* isolates were recovered from Tripoli University Hospital, Tripoli, Libya and coded as AS-185 and SA-325. The identification and antibiotic sensitivity were carried out for these isolates by Biomerux VITEK2 automated system Version 05.04 (BioMérieux Inc.) at microbiology laboratory, Tripoli university hospital. Stock solution of biosynthesized Ag-NPs (5 mg/ml) was prepared in distilled water then the antibacterial activity was determined against MDR *S. aureus* AS-185 and SA-325. This assay was performed using agar well diffusion technique, in which, wells (8 mm) were cut in Muller Hinton agar (Merck KgaA, Germany) plates inoculated with tested bacteria. Fifty microlitres of AgNPs solution were pipetted into each well. After incubation at 37 °C for 24 h, the inhibition zone diameter around each well was measured in mm Antibiotic paper disks of Penicillin and vancomycin were used for comparison in this assay that was carried out according to Kirby-Bauer method according to (Bauer *et al.*, 1966; Moghannem *et al.*, 2017).

### Assessment of AgNPs synergistic activity in combination with antibiotics

To determine the synergistic effect of AgNPs in combination with antibiotics, different antibiotics belong to different classes of antibiotics: Amoxicillin, Amoxicillin-clavulanate, Cefoxitin, Cefuroxime, Ciprofloxacin, Erythromycin, Gentamicin, Methicillin, Nalidixic acid, Neomycin, Oxacillin, Penicillin, Polymyxin B, and Tetracycline were used. A disc diffusion method was performed to screen the synergistic activity of AgNPs and antibiotics. All antibiotics were used in the form of standard antibiotic discs 6mm in diameter (HiMedia Laboratories Pvt. Ltd, Mumbai, Maharashtra, India). Bacterial suspension of MDR *S. aureus* AS-185 and SA-325 were spread on MHA plates then, standard antibiotic disk was impregnated with 25 µl of prepared AgNPs (0.25 mg/ml) and gently placed on the MHA plates as well as standard antibiotic disk without AgNPs and impregnated paper disk at the same concentration. After 48 h of incubation at 37 °C, the inhibition zone (mm) was measured. This assay was performed in triplicate and the increase in fold area was estimated by measuring the mean of the inhibition zone produced by an antibiotic alone and in combination with AgNPs, according to the following equation:

$$\text{The fold increase area} = \frac{(B^2 - A^2)}{(A^2)}$$

Where **A** is ZOI for the antibiotic and **B** is ZOI for the antibiotic + Ag-NPs (Birla et al., 2009).

## RESULTS AND DISCUSSION

### Isolation and Screening of Actinobacteria for Extracellular biosynthesis of AgNPs

Actinobacterial isolates were recovered from soil samples and purified by streaking on SNA medium. These isolates were screened for extracellular biosynthesis

of Ag-NPs. According to this screening, the isolate MFA-37 was selected. The color of reaction mixture changed from light yellow to dark brown at end of incubation time. No color change was observed during incubation of both silver nitrate solution and cell free supernatant without AgNO<sub>3</sub> (Fig. 1-A & 1-B). The UV-Visible spectra of silver nitrate solution, cell free supernatant of actinobacterial isolate MFA-37 and reaction mixture were completely different and the reaction mixture of AgNPs was seemed the highest absorbance at 400- 450 nm (Fig. 2).

The change in color of the reaction mixture may attributed to the reducing and capping potential substances present in the cell free supernatant of actinobacterial isolate MFA-37. The brown color of the Ag-NPs is due to excitation of surface plasmon vibration in Ag-NPs (Phanjom & Ahmed, 2015). It is observed from Figure (1-C) that the synthesized AgNPs display a clear and single surface plasmon resonance (SPR) peak located at 400-450 nm which confirms the reduction of silver ion to metallic silver. Metal nanoparticles have free electrons, which yield a surface plasmon resonance (SPR) absorption band, due to the mutual vibration of electrons of metal nanoparticles in resonance with light wave. The appearances of the peaks show the characteristics of surface plasmon resonance of Ag-NPs (Anandalakshmi *et al.*, 2016).

**Fig. (1): Photographs of biosynthesis of silver nanoparticle(A):  $\text{AgNO}_3$ , (B): cell free supernatant of actinobacterial isolate MFA-37, and (C): reaction mixture after 24 h.**

### Characterization of actinobacterial isolate MFA-37

#### Morphological characteristics

Microscopic examination of actinobacterial isolate MFA-37 grown on SNA medium at  $28^\circ\text{C}$  for 7 days (Fig. 3-A) using slide culture technique indicated that, aerial mycelium was long rectiflexible to spiral with open loop bearing spore chain. Transmission electron microscopy was confirmed that, each spore chain contains more than 30 cylindrical spores with smooth surface (Fig. 3-B and 3-C).

#### Culture characteristics

Culture characteristics of isolate MFA-37 were noted after their cultivation on different International Streptomyces Project (ISP) media. This isolate was grown well on ISP-3, ISP-5, ISP-7 and SNA media while the growth on ISP-2, ISP-4 and ISP-6 was moderate. It produced white to grey powdery colonies on the surface of agar while reversed side varied between light yellow to brown without diffusible pigment on all ISP and SNA media (Table 1).

**Fig.(3): photograph of culture isolate MFA-37 on SNA medium(A), Spore chain bearing hyphae by light microscopy (X800) (B) and Spore chain arrangement and spore surface by TEM; (X10000) (C).**

### Physiological and biochemical characteristics

Isolate MFA-37 grows well on ISP-9 medium amended with different types of sugars that was used as a sole carbon source. The growth was observed at a wide range of temperature (15 – 40 nm). NaCl

concentrations suppressed the growth starting from 5% and above. The isolate succeeded to grow on Czapek's medium as shown in Table (2). The morphological, physiological and cultural characteristics indicated that the soil isolate belonged to the genus *Streptomyces*.

**Table 1: Culture characteristics of isolate MFA-37on different ISP media**

Medium	Aerial mycelium	Substrate mycelium	Diffusible pigment	Growth density
Yeast extract malt extract agar medium (ISP-2)	White	Brown	No	Moderate
Oatmeal agar medium (ISP-3)	Grey	Light yellow	No	Good
Inorganic salts starch agar medium (ISP-4)	White	Yellow	No	Moderate
Glycerol - asparagine agar medium (ISP-5)	Grey	Light brown	No	Good
Peptone yeast extract iron agar medium (ISP-6)	Creamy	Light brown	No	Moderate
Tyrosine agar medium (ISP-7)	White	Brown	No	Good
Starch nitrate agar (SNA)	Grey	Light brown	No	Very good

### Molecular characterization

The molecular identification of isolate MFA-37 using 16s rRNA gene was performed. The small subunit of rRNA (16S) was amplified using universal primers RW01 and DG74 and sequenced resulting in partial nucleotide sequences of 480bps. The obtained sequence of isolate MFA-37 was compared with available 16S rDNA sequences in the Gen Bank databases using BLASTn tool and the present data referred to that, the isolate MFA-37 belonged to genus *Streptomyces* with greatest homology (97%) to *S. rochei* published sequences. The partial sequence of 16S rDNA of isolate MFA-37 was deposited in Gen Bank under the accession number MH577306.A multiple sequence alignment was constructed between the isolate MFA-37 and

reference strains. Phylogenetic analysis was performed by construction of phylogenetic tree using a neighbor joining method to describe the relationships among all *Streptomyces* isolates (data not shown).

The resulted sequence was aligned with available almost complete sequence of type strains of family streptomycetaceae. It formed separate clade that was closely related to *Streptomyces rochei* strain NRRL B-1559 sharing 16s rRNA gene similarity matrix is 97% with this species and others but, the results of microscopic, physiological and biochemical characteristics of isolate MFA-37 suggest that this isolate is *Streptomyces rochei* strain MFA-37 according to Hensyl (1994).

**Table 2: Physiological and biochemical characteristics of isolate MFA-37**

Characteristics	Results	Characteristics	Results
<b>Utilization of carbon sources</b>		<b>Growth at different temperatures (°C)</b>

### Characterization of Ag-NPs

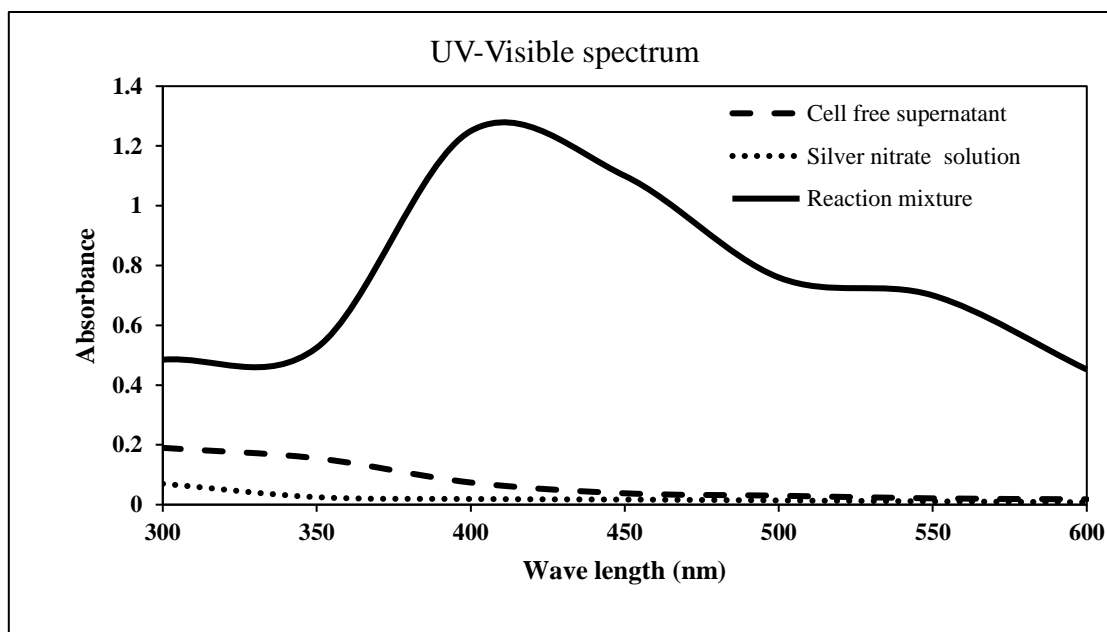

#### Ultra Violet-Visible Spectroscopy (UV-Vis)

The biosynthesized AgNPs were characterized by UV-visible spectroscopy, which has been shown to be a valuable and important tool for the analysis of metal nanoparticles. In the UV- visible spectrum, a strong, broad peak at about 440 nm was observed for AgNPs indicating the presence of AgNPs (Fig. 4). In agreement with previous reports, the absorption peak between 400 and 450 nm clearly indicates the formation of Ag-NPs and this due to the excitation of plasmon resonance (Manikprabhu & Lingappa, 2013; and Kumar *et al.*, 2015).

#### Fourier Transform Infrared (FTIR) Spectroscopy analysis

The FTIR analysis was used for the characterization of AgNPs in cell free

filtrate *Streptomyces rochei* strain MFA-37. FTIR assessment revealed the ranges between 400 to 4000  $\text{cm}^{-1}$  (Fig. 5). The IR analysis showed the following: the sharp peaks at 3448.7  $\text{cm}^{-1}$  were indicative of the N-H stretching of amides, the peak at 1635.6  $\text{cm}^{-1}$  were attributed to the N-H bending of amines, the peak at 1396.4  $\text{cm}^{-1}$  was ascribed to the NO<sub>2</sub> asymmetric stretching of nitro compounds, the peak at 1087.85  $\text{cm}^{-1}$  was attributed to the C-N stretching of amines, the peak at 1087.8  $\text{cm}^{-1}$  was attributed to the C-N stretching of amines and 563.21  $\text{cm}^{-1}$  (C-Br stretch of alkyl halides). FTIR were carried out to identify the biomolecules for capping and efficient stabilization of the metal nanoparticles synthesized. From the analysis of FTIR studies we concluded that the amide and amine groups from the amino acid residues and proteins have the stronger ability to bind metal to prevent agglomeration and thereby

**Fig. (4): The UV/V is spectrum of the Ag-NPs synthesized by *Streptomyces rochei* strain MFA-37.**

stabilize the medium. This suggests that the biological molecules could possibly perform dual functions of formation and stabilization of Ag-NPs in the aqueous medium (Majeed *et al.*, 2016).

#### **Size and morphology analysis of AgNPs using HR-TEM**

HR-TEM micrographs of the biosynthesized AgNPs revealed distinct, uniformly crystalline and a quasi-spherical structure of the Ag-NPs in the reaction solution. These nanoparticles were well separated from each other. The average particle size was estimated from measuring particles representing different size from TEM images and showed particle sizes between 2 and 20 nm (Fig. 6).

Several reports revealed that, the extracellular biosynthesized AgNPs are predominantly spherical in shape (Raut *et al.*, 2009; Deepa *et al.*, 2013) reported that Ag-NPs synthesized from marine Actinobacteria

shows size of nanoparticles ranging from 20 to 30 nm.

#### **X-ray diffractometry**

The crystalline nature of biosynthesized Ag-NPs was analysed using powder X-Ray diffractometer. This method was used to confirm the particles as silver and identify the phase composition, crystalline structure and size of the biosynthesized Ag-NPs (Daphedar & Taranath, 2018). The data represented in (Fig. 7) show the XRD pattern of Ag-NPs. The pattern clearly shows the main peaks at  $2\theta$  38.19, 44.37, 64.56 and 77.47 corresponding to the (111), (200), (220) and (311) planes, respectively. By comparing JCPDS (file no: 89-3722), The XRD pattern thus clearly illustrates that the Ag-NPs formed in this present synthesis are crystalline in nature and having face centred cubic (fcc) crystal structure.

**Fig. (5): The FTIR spectrum of the Ag-NPs synthesized by *Streptomyces rochei* strain MFA-37.**

The average crystalline size of the Ag-NPs was determined, and their average size found to be 14 nm.

### Particle size distribution

Dynamic light scattering (DLS) is a valuable technique to evaluate particle size, and size distribution of nanomaterials in solution. DLS was carried out to determine particle size in aqueous solutions and Laser diffraction studies revealed that particle size obtained from DLS were monodisperse in nature and are in the range of  $14.2 \pm 1.6$  nm (Fig. 8). Saha et al. (2010) reported that the particle size distribution of Ag-NPs synthesized by phytopathogenic fungus *Bipolaris nodulosa* using its mycelia free media shows that particles are monodisperse mixture, with particle size 10-60 nm.

### Potential measurement

The zeta potential value is the total number of charges of the functional group with a negative charge on the surface of AgNPs (Borase et al., 2013). In this study, the zeta potential value of the dispersed Ag-NPs in distilled water recorded -20.5 mV as shown in Figure (9). This value indicates

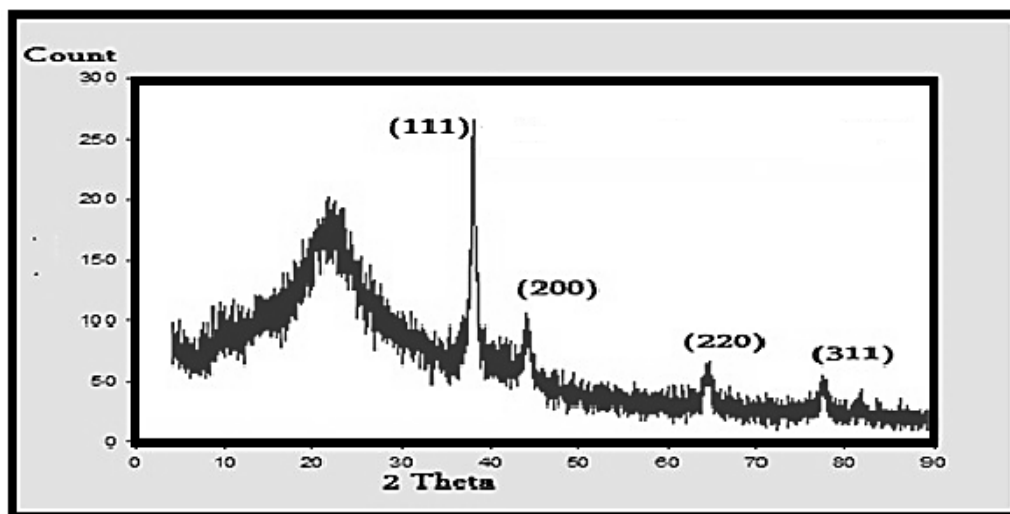

that Ag-NPs produced in this study are stable, and suitable for long-term storage, and with this charge also became more dispersed and were difficult to agglomerate and this similar to finding by Jinmeng et al. (2017) who indicate that the potential value of AgNPs that was synthesized from rice straw biomass was -21.2 mV and they concluded that those nanoparticles charge made it good stable and suitable for long-term storage and the higher absolute value is made nanoparticles in suspension more stability.

### Antibacterial activity of AgNPs

In the present investigation, the antibacterial activity of biosynthesized AgNPs was determined against MDR *S. aureus* SA-185 and SA-325 clinical isolate by agar diffusion method. The results indicated that AgNPs exhibited antibacterial effect with inhibition zone (22 mm) also vancomycin showed an inhibition zone of 22 mm, on the other hand, penicillin seemed as ineffective against both isolates (Fig. 10). The formation of inhibition zone around the well was an indication of antibacterial activity of Ag-NPs (Narasimha et al., 2013).

**Fig. (6):**HR-TEM image of the AgNPs formed by the reaction of 1mM AgNO<sub>3</sub> and the cell-free supernatant of *Streptomyces rochei* strain MFA-37, Scale bar = 50nm.

**Fig. (7):** XRD pattern of synthesized Ag-NPs by *Streptomyces rochei* strain MFA-37.

Both vancomycin and penicillin were used as positive and negative control respectively to compare their action with the action of biosynthesized AgNPs against this clinical isolate. The selection of these two types of antibiotics was done according to their antibiotic profile which determined manually and automatically using paper disc agar diffusion method and vitek2 system respectively.

#### Assessment of AgNPs synergistic activity in combination with antibiotics

In the current study, the efficacy of biosynthesized AgNPs alone and in combination with different antibiotics was studied against MDRS. *aureus* AS-185 and SA-325 clinical isolate using the disc diffusion method. Antibiotics used in this study belong to different groups and had different modes of action as indicated in the Table (3).

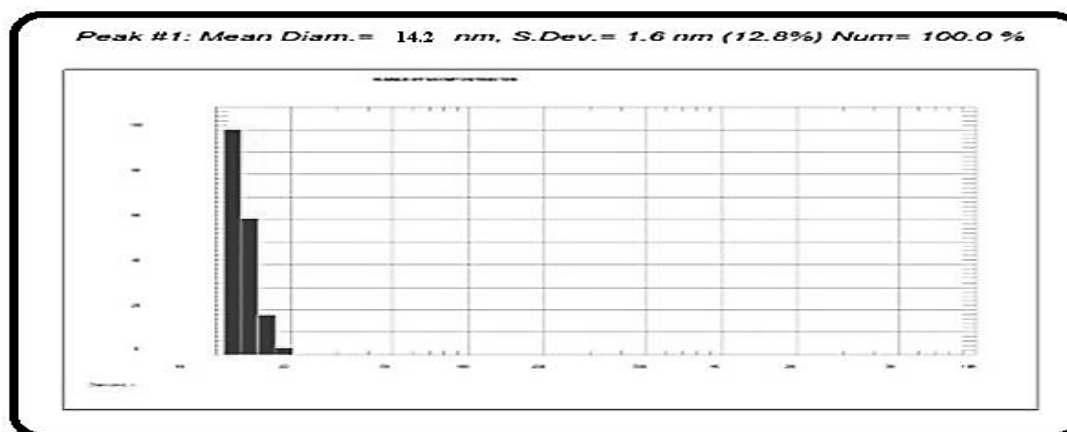

Fig. (8): DLS pattern of synthesized Ag-NPs by *Streptomyces rochei* strain MFA-37.

Generally, the Ag-NPs enhanced the antimicrobial activity of all tested antibiotics with a different degree for both organisms (Table 3), where the Increase in fold area varied from one antibiotic to another. and also differ in both tested isolates, the increase varied from 0.15 to 6.37-fold. There was an increase in antimicrobial activities of all antibiotics when combined with AgNPs. There was an increase in antimicrobial activities of all antibiotics when combined with AgNPs that suggests that these can enhance the activity of these antibiotics, which may be promising drugs for the treatment of MRSA infectious disease, especially the superficial injuries.

Interestingly, amongst the selected antibiotics, penicillin in combination with

Ag-NPs showed the highest activity against two tested bacteria (Table 3). These results similar to the findings of Birla *et al.* (2009) who mentioned increasing efficacies (percentage) of antibiotics like vancomycin, gentamycin, streptomycin, ampicillin, and kanamycin when used in combination with AgNPs against *P. aeruginosa*, *S. aureus*, and *E. coli*. Fayaz *et al.* (2010) assessed the antibacterial activities of ampicillin, chloramphenicol, erythromycin, and kanamycin combined with AgNPs against Gram-negative and Gram-positive bacteria, they concluded that the antibacterial activity of all antibiotics increased in the presence of AgNPs. Moreover, the highest synergistic effect was observed with ampicillin.

Fig. (9): Zeta potential of synthesized Ag-NPs by *Streptomyces rochei* strain MFA-37.

**Fig. (10): Antibacterial activity of AgNPs, penicillin and vancomycin against MDRS. aureus SA-325.**

**In the absence of bacterial growth inhibition zones, the disc's diameter (6 mm) was used to calculate according to this equation: increase in fold area = (b2 - a2)/a2. Mean diameter of inhibition zone of only AgNPs is 15.4 mm.**

## Conclusion

This study represents an effective synthesis method of Ag NPs via greenway using cell-free filtrate of *Streptomyces rochei* strain MFA-37 as bio-reductant and capping agents. Physical characterization indicates that the biological synthesis of Ag-NPs in a crystalline form ranged in size 2–20 nm. The antibacterial activity of the particles was tested against multi-drug resistant *S. aureus* strains and showed high effectiveness against the tested bacteria. The combination of AgNPs with different antibiotics with a different mode of action was also screened and the study

demonstrates the synergistic effect of antibiotics and nanoparticles which can be effectively used in order to improve their efficacy against *S. aureus* strains as a model of pathogenic microbes. AgNPs were found to be most effective with the antibiotics inhibiting cell wall synthesis followed by protein synthesis and nucleic acid synthesis against tested *S. aureus* strains. The feature of enhancement of the antibacterial potential of antibiotics using biosynthesized AgNPs can be utilized in the development of enhancement of antibiotic activity.

## Acknowledgments

The authors are thankful to the Department of Microbiology, Ain shams University, Cairo, Egypt and to the Department of Botany and Microbiology, Al-Azhar University, Cairo, Egypt, for providing necessary laboratory facilities to execute these studies. The authors are very grateful to Microbiology laboratory, Tripoli University Hospital for providing the resistant *S. aureus* SA-185 and SA- 325 from clinical patients.

### المستخلص

عملية التخليق الحيوي للجسيمات النانوية تعتبر من الطرق الواعدة، فهي رخيصة نسبياً وصديقة للبيئة. من بين مختلف الكائنات الحية الدقيقة، تعتبر البكتريا الحيطية من أهم الكائنات فاعلية في تخليق الجسيمات النانوية. في هذا العمل، تم التخليق الحيوي لجسيمات الفضة النانوية خارج الخلية (Ag-NPs) من خلال مزج نترات الفضة مع راشح مزرعة البكتريا سترپتومييسس روتشي السلالة MFA-37. تم الاستدلال على تخليق جسيمات الفضة النانوية من خلال التحليل الطيفي للأشعة المرئية والفوق البنفسجية (UV-Vis spectrum)، حيث أظهرت المزيج ذروة امتصاص عند الطول الموجي 440 نانومتر. كذلك أظهر تحليل طيف الأشعة تحت الحمراء (FTIR) إلى وجود مجاميع الأمينات والأميدات التي قد تكون المسؤولة عن استقرار هذه الجسيمات. شكل وحجم الجسيمات النانوية تم تحديدها باستخدام تقنية المجهر الإلكتروني النافذ عالي الدقة (HR-TEM) وتقنية تشتت الضوء الديناميكي (DLS) وتقنية حيود اشعة أكس (XRD) والتي أشارت بأن جسيمات الفضة النانوية تتميز بأنها كروية الشكل بحجم يتراوح من 2 إلى 20 نانومتر، ذات توزيع متجانس في المحلول بشكل جيد، وعند تقدير شحنة هذه الجسيمات بجهد زيتا (Zeta potential) وصلت إلى -20.5 ملي فولت. وقد أجري تعزيز للنشاط الضد بكتيري لأربعة عشر مضاداً حيوياً عن طريق الجمع بين هذه المضادات الحيوية المختلفة مع جسيمات الفضة النانوية المخلقة حيوياً. تم تحديد النشاط التأزري للمزيج ما بين جسيمات الفضة النانوية وهذه المضادات الحيوية باستخدام طريقة انتشار الأقراص على agar ضد اثنين من سلالات المكورات العنقودية الذهبية المقاومة للادوية المتعددة SA-185 و SA-325 المعزولة من ليبيا. كان أعلى تأثير تأزري لهذه الجسيمات مع البنسيلين 6.11 و 6.37 مرة، يليه السبروفلوكساسين 6.11 و 4.44 مرة، ثم الارثروميسين 6.11 و 3.69 مرة لكل من السلالة SA-185 والسلالة SA-325 علي التوالي.

وقد أتضح من نتائج الدراسة إن هذا النشاط لمزيج جسيمات الفضة النانوية والمضادات الحيوية يمكن أن يكون له قيمه علاجية لتصنيع الادوية الهجينة لقتل أو منع العدوي البكتيرية المتسببة بواسطة المكورات العنقودية الذهبية المقاومة للادوية المتعددة خاصه في حاله الإصابات السطحية.
